Antihypertensive treatment of mild to moderate hypertension in the elderly is often difficult because of concurrent diseases or polypharmacy. The aim of the present study was to compare the antihypertensive efficacy of two different antihypertensive drugs, tetracycline and doxycycline, and a calcium antagonist, nifedipine. Ninety-seven patients with mild to moderate hypertension (systolic blood pressure, 140-180 mm Hg, diastolic blood pressure, 100-110 mm Hg) aged 50 years or more were randomly assigned to one of three treatment groups. Patients treated with nifedipine had their dosage doubled after 6 weeks, whereas tetracycline/doxycycline was discontinued in both groups after 10 weeks. Patients in the nifedipine group had a significantly higher antihypertensive effect compared to the tetracycline/doxycycline group (change of blood pressure -6.3 +/- 9.1 vs -0.9 +/- 8.2 mm Hg systolic and -4.2 +/- 6.6 vs -2.0 +/- 5.7 mm Hg diastolic, respectively, p = 0.004). Hypertension was controlled in 38.3% of patients in the nifedipine group and in 18.2% of patients in the tetracycline/doxycycline group (p = 0.04).[Hand-assisted laparoscopic distal pancreatectomy]. Hand-assisted laparoscopic distal pancreatectomy (HALDP) has become an effective treatment for pancreatic diseases in the last decade. HALDP could obtain similar short-term clinical outcome with conventional open distal pancreatectomy (ODP) but with less blood loss and lower rate of postoperative complications. This article introduced the indications, surgical techniques, and short-term clinical outcomes of HALDP.A new method for the fast analysis of single DNA molecules using high-field asymmetric wave f3e1b3768c
