Decoding the evolutionary mechanisms underlying the allometric relationship between body mass and appendicular length of the white-throated spider monkey (Ateles belzebuth). Body mass and morphology are traditionally considered to be evolutionarily stable characteristics. Their covariation is commonly explained by the trade-off hypothesis. The trade-off hypothesis is supported by the observation that the allometric relationship between body mass and appendicular length is almost identical in humans and great apes. In contrast, the allometric relationship has evolved differently in the tribe Atelini: the allometric exponent of body mass to appendicular length is almost two times greater in white-throated spider monkey (Ateles belzebuth) than in humans and great apes. Here we tested if the increase in body mass of Ateles belzebuth is related to changes in scaling of the hind limb. The allometric relationship between body mass and tibial length was similar to that of humans and great apes and the allometric exponent of body mass to tibial length was comparable to that of humans and great apes. These results suggest that the lower allometric relationship between body mass and appendicular length in Ateles belzebuth is not related to changes in the scaling of the hind limb and may be a result of a change in the scaling of other regions.
