The accumulation of tetraethylammonium (TEA) was measured by fluorescence quenching and permeability studies. In inside-out and outside-in models, the uptake was temperature-dependent, saturable, and energy-dependent. TEA flux into cells was found to be correlated with membrane potential. Preincubation of the cells with ruthenium red, an inhibitor of Ca<sup>2+</sup> transport in the plasma membrane, resulted in decreased flux and increased extracellular accumulation of TEA. These results indicate that TEA uptake in the plasma membrane is linked to the transport of calcium. In plasma membrane vesicles, TEA flux was temperature-dependent and increased linearly with protein concentration. TEA influx in inside-out and outside-in plasma membrane vesicles was dependent on the presence of membrane potential, a gradient of monovalent cations, and sodium in the external medium. Vesicles from cells preincubated with a calcium-free medium showed a marked increase in TEA flux, and this flux was strongly inhibited by ruthenium red. These data indicate that TEA is transported into the plasma membrane by a potential-dependent, monovalent cation-selective, energy-dependent process, and that this transport is associated with the active transport of Ca<sup>2+</sup> into the cells.Philip's just fine with the sale of Bellingham.
