An electroencephalogram (EEG) microstate model using spatiotemporal dynamics based on physiological parameters (SPD) was recently introduced by our group. This is an EEG model that exhibits the specific characteristics of the physiological processes of the human brain by determining the microstate as the unspecific locations of the independent sources of EEG dynamics based on the physiological parameters. In addition, we expect that the SPD model will provide new information about physiological aspects of the human brain. This study was conducted to investigate the information content of the SPD model and compare the performance of the model based on a conventional and a new approach. Therefore, we used the posterior probabilities of a non-compound model and a new model to extract the information of the SPD model and the N-back test to compare the SPD model and the conventional model in terms of information content. The results showed that the SPD model with a higher information content than the conventional model for a recognition memory test, and that the SPD model exhibited more specificity than the conventional model for a working memory test. In addition, the SPD model showed a correlation with the behavioral performance. Based on these results, the new model may be useful for the identification of the physiological states of the brain and the assessment of cognitive states. The non-natural amino acid 1-aza-4-butanone is a potent, specific, irreversible and cell-permeable inhibitor of the hypoxic factor HIF-1alpha. Hypoxia-inducible factor (HIF)-1alpha plays a central role in hypoxic adaptation by inducing the expression of target genes. HIF-1alpha is degraded by oxygen-dependent hydroxylation of proline residues within its oxygen-dependent degradation domain (ODDD). In hypoxic cells, ODDD hydroxylation is blocked, resulting in the stabilization and accumulation of HIF-1alpha. To identify specific inhibitors of HIF-1alpha hydroxyl 2d92ce491b
