The goal of this research project is to develop an integrated high-throughput proteomic screening approach to assay for human cancer biomarkers. In particular, we wish to develop a method for the simultaneous screening of a large number of individual human sera for multiple cancer biomarkers using a set of both targeted and untargeted protein chips. This high-throughput proteomic assay will allow us to apply a new "omics" strategy for biomarker discovery, i.e., using a whole-human proteomic analysis rather than a single protein as the parameter for disease diagnosis. This approach may not only provide a simplified approach for the rapid identification of multiple cancer biomarkers from serum samples, but will also simultaneously assay for hundreds or thousands of biomarkers from a single sample, allowing us to generate a comprehensive cancer biomarker profile.
