The development of artificial blood substitutes, based on polymers, has been the subject of considerable interest for many years. There are a number of applications of these materials in medicine, such as emergency treatment of blood loss due to trauma or hemorrhage, storage of blood products prior to transfusion, and research into the potential application of oxygen delivery to tissues, for example. The ideal artificial blood should have the same hematological and biochemical parameters as normal blood, and preferably a molecular weight that is closely matched to that of the blood. It should have physicochemical properties close to those of natural plasma and should be free of infectious agents. Furthermore, it should not interact with the natural blood components, and it should not produce the unwanted side effects that occur with conventional drugs. It should have a low volume of distribution (and hence have a high efficiency for delivering oxygen), and should have a suitable molecular weight to give a sufficiently large molecular surface area which will allow adsorption or encapsulation of a sufficient amount of oxygen to form a stable blood substitute. In addition, the blood substitute should have the ability to release oxygen by chemical, physical or biochemical mechanisms when oxygen demand increases, and ideally should be able to remove released or stored oxygen when oxygen demand decreases. Ideally, it should also be stable during storage for a reasonable time and at ambient temperature. A number of polymers have been synthesized with the aim of producing an artificial blood substitute. These include polyethylene glycol (PEG), poly(2-hydroxyethyl methacrylate) (PHEMA), polyvinyl alcohol (PVA), polyvinyl pyrrolidone (PVP), polyvinylpyridine (PVPy), polypropylene oxide (PPO), polysulfones (PSUs), polyethylene imine (PEI) and polyethylene glycol-tetra-methyl ammonium (PGMA-TMAM 82138339de
