Hand burns are one of the more common injuries encountered in the emergency room and plastic surgical practice. Despite the variety of anatomical structures in the human hand, good local tissue coverage and primary-approximation of the injured structures can be obtained in hand burns of moderate size and location. Complete necrosis of skin, however, can occur after the first 24 hours in patients with trauma of moderate size and depth. Such injury usually necessitates resection of all necrotic skin and skin

Field of the Invention The present invention relates to a silver halide color photographic light-sensitive material. 2. Description of the Related Art Conventionally, there are known a silver halide color photographic light-sensitive material, for example, silver chlorobromide (containing 40 to 90 mol % of silver chloride) as a silver halide of the blue sensitive layer, silver chlorobromide (containing 70 to 95 mol % of silver chloride) as a silver halide of the green sensitive layer and silver chlorobromide (containing 40 to 80 mol % of silver chloride) as a silver halide of the red sensitive layer, and silver chloride is used as a silver halide of the yellow sensitive layer. Since the color reproducibility of a yellow sensitive layer is poor, there are proposed methods in which a sensitizing dye is contained in a yellow sensitive layer in order to improve the color reproducibility. For example, there are known a method in which a sensitizing dye is introduced at the beginning of the ripening or the use of a sensitizing dye which can be added at a high concentration, a method in which a layer is formed using a sensitizing dye such that the sensitizing dye moves to a deep portion of the layer, etc. As a result of the introduction of a sensitizing dye, the sensitivity is improved, and the quality of a color print (e.g., the color reproducibility of a reproduced color and the gradation of a reproduced color) is improved. On the other hand, in recent years, the request for miniaturization of a silver halide light-sensitive material is increasing, and accordingly the diameters of emulsion grains are decreasing from 3 µm to 2 µm to 1 µm, and the diameters
