of radiation, including low transmission loss, small size, and fast response times. One application which utilizes lasers is wavelength division multiplexing, or WDM. WDM can be employed in large-capacity telecommunications networks, where it offers increased capacity and reduced costs. The photonic structures that can be employed in WDM systems are well understood. The primary requirement is that these structures must operate over a narrow spectral range, with high and low attenuation. For telecommunications applications, operating over a spectral range from around 1.2 microns to 1.55 microns is desirable. Optical fibers have been employed in telecommunications applications to transfer information, allowing large distances and high bandwidths. The principal drawback to optical fibers has been their relatively high attenuation in the transmission of radiation at wavelengths shorter than 0.8 micron. An advantage of the use of radiation at optical wavelengths in telecommunications applications has been the small size of many of the components that can be utilized. Optical fibers typically have a diameter of 125 microns or less, and a standard telecommunications fiber requires only a 1.25-micron-diameter core surrounded by a 0.25-micron-diameter cladding. A photonic structure that has many useful properties is a structure in which the transverse profile of light is changed by surface plasmonic modes. Such structures can be made using surface plasmonic gratings, which are distinct from surface plasmon mode based structures.
