Guides and Licenses and Manage Serial. Adobe Acrobat Pro DC.To allow successful folding and randomization of single domain polypeptides to yield proteins of correct size and stability, the efficiency of translation termination is the one determining factor, in addition to the rate of incorporation of the aminoacyl-tRNAs. We have previously shown that the translation termination efficiency is higher for sequences that contain a long run of four hydrophobic amino acids in the middle of the coding region. These include the stop signal, UGA, which is the least stable codon, and UCU, which is more stable than UAA (E9 and G1, respectively). We also found that the addition of dDcm, which is stable in the wobble position of UGA and UCU, improves the translation termination efficiency of these codons. We have now found that dDcm interacts with the ribosome and binds to the ribosome at the region immediately adjacent to the anti-Shine-Dalgarno site. We will therefore explore the function of this interaction in termination by chemical cross-linking, and determine the ribosome structure in a near-atomic resolution model. We plan to look for additional compounds that interact with the ribosome in a similar way. If these compounds can be found, they should aid in the crystallization of the ribosome. We will also search the ribosome for additional long runs of hydrophobic amino acids, and explore their function as translation termination signals. Lastly, we will determine whether our combined findings can be extended to other codons.

The present invention relates to medical devices and more particularly to a device for the localization of a mass or region of tissue. An early example of such a device is a positron emission tomography scanner of the type described in U.S. Pat. Nos. 4,035,487 and 4,175,532. Positron emission tomography scanners use the principles of positron emission tomography to provide images of certain chemical entities that, when they are incorporated into a biologically active molecule, are located and can be tracked within the body. An image of the distribution of a biological entity is obtained by detecting the positrons emitted from the biological entity after it has been annihilated by an electron, or pair of electrons, within the body.

The invention relates specifically to a hyperpolarization technique for enhancing the detection of annihilation pairs, thereby increasing the resolution of the resulting image. The hyperpolarization technique permits the use of positrons emitted from biological entities that are a part of the living body as the principal detection mechanism. At a given temperature, the fraction of a thermodynamically available number of positrons that can be trapped and detected is less than unity. In contrast, by hyperpolarizing or orienting the positrons in an appropriate magnetic field, the fraction of thermodynamically available positrons that can be trapped and detected increases to unity. Thus, hyperpolarization allows the detection of lower
